

The Spotify 2023 dataset was imported into Power BI for analysis and visualization. The data was cleaned and relevant numerical fields were aggregated using measures such as Sum and Average. Different charts were created to analyse audio features, platform chart presence, artist involvement, and trends over release years. Filters and visual comparisons were used to identify patterns and relationships in the dataset.

Music Analysis

The analysis examines audio characteristics such as danceability, energy, acousticness, instrumentalness, liveness, speechiness, and valence. These features help describe the characteristics of songs included in the dataset.

Danceability vs Song Streams

Sum of danceability_% and Sum of streams by track_name

Average of instrumentalness_%, Average of liveness_%, Average of energy_%, Average of valence_%, Average of speechiness_%, Average of acousticness_% and Average of danceability_%

Platform Comparison

Spotify, Apple Music, Deezer, and Shazam chart-related measures were compared to examine the presence of songs across different platforms. The results show differences in average chart presence between platforms.

Artist comparissons

Songs involving different numbers of artists were compared using their average streams. The analysis also identifies the top artists based on average streams within the dataset.

Temporal Trends

Release years were used to examine changes in average streams and audio characteristics over time. The visualizations show how danceability, energy, and valence vary across release years.

Cross-Platform Presence

Chart-related measures from Spotify, Apple Music, Deezer, and Shazam were compared to understand how songs represented in the dataset appear across multiple music platforms.
